# Week 5, Lecture 10 - Hidden Markov Models

Aaron Meyer

#### Outline

- Administrative Issues
- Review
- Hidden Markov Models
- Applications

Based on slides from Aarti Singh.

# Sequential Data

- So far we've largely assumed that we have independent data
- But what if we have sequences?
  - ► E.g. audio, a string of text, time-series data
  - ► Then our measurements are co-dependent
  - Assumption of independence often gives nonsensical results

#### Markov Models

- ▶ Joint Distribution
  - $p(\mathbf{X}) = p(X_1, X_2, \dots, X_n)$
  - $p(\mathbf{X}) = p(X_1)p(X_2 \mid X_1)p(X_3 \mid X_2, X_1) \dots p(X_n \mid X_{n-1}, \dots, X_1)$
  - $ightharpoonup \prod_{i=1}^{n} p(X_n \mid X_{n-1}, \dots, X_1)$ 
    - Chain rule
- Markov Assumption
  - - Current observation only depends on past m observations

#### Markov Models

#### Markov Assumption

$$p(\mathbf{X}) = \prod_{i=1}^{n} p(X_n | X_{n-1})$$

# 2<sup>nd</sup> order

$$p(\mathbf{X}) = \prod_{n=1}^{n} p(X_n | X_{n-1}, X_{n-2})$$

#### Markov Models

#### Markov Assumption

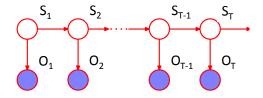

The number of parameters in a stationary model with K-ary variables

- ▶ 1st Order
  - $p(\mathbf{X}) = \prod_{i=1}^{n} p(X_n \mid X_{n-1})$   $O(K^2)$
- ▶ mth Order
  - $p(\mathbf{X}) = \prod_{i=1}^{n} p(X_n \mid X_{n-1}, \dots, X_{n-m})$   $O(K^{m+1})$
- ightharpoonup n-1th Order
  - $p(\mathbf{X}) = \prod_{i=1}^{n} p(X_n \mid X_{n-1}, \dots, X_1)$
  - $ightharpoonup O(K^n)$
  - No assumptions: Complete (but directed) graph

Homogeneous/stationary Markov model (probabilities don't depend on n)

#### Hidden Markov Models

Distributions that characterize sequential data with few parameters but are not limited by strong Markov assumptions.

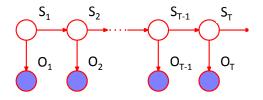

Observation space:  $O_t \in \{y_1, \dots, y_k\}$ 

Hidden states:  $S_t \in \{1, \dots, I\}$ 

7 / 4

#### Hidden Markov Models

$$p(S_1, \dots, S_T, O_1, \dots, O_T) = \prod_{t=1}^T p(O_t \mid S_t) \prod_{t=1}^T p(S_t \mid S_{t-1})$$

1st order Markov assumption on hidden states  $\{S_t\}$   $t=1,\ldots,T$  (can be extended to higher order).

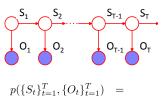

Note:  $O_t$  depends on all previous observations  $\{O_{t-1}, \ldots O_1\}$ 

/ 4

#### Hidden Markov Models

#### Parameters for stationary/homogeneous Markov model

- ightharpoonup Independent of T
- ▶ Initial probabilities:  $p(S_1 = i) = \pi_i$
- ▶ Transition probabilities:  $p(S_t = j \mid S_{t-1} = i) = p_{ij}$
- ▶ Emission probabilities:  $p(O_t = y \mid S_t = i) = q_i^y$

$$\{\{S_t\}_{t=1}^I, \{O_t\}_{t=1}^I\} = p(S_1) \prod_{t=2}^T p(S_t|S_{t-1}) \prod_{t=1}^T p(O_t|S_t)$$

) / 43

# **HMM** Example

#### The Dishonest Casino

A casino has two die:

- ► Fair dice
- Loaded dice:

$$P(6) = 1/2, P(1) = P(2) = P(3) = P(4) = P(5) = 1/10$$

Casino player switches back & forth between fair and loaded die once every 20 turns.

#### **HMM** Problems

**Given:** A sequence of rolls by the casino player:

4352**6**1**6**25434**6**1**6**52**6**53421**6**515243**6**1**6**1524324131514

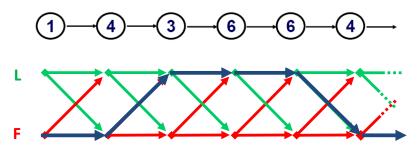

322515432**6**3**6**43**6**2**6**541415145312

#### Questions:

- How likely is this sequence, given our model of how the casino works?
  - ► This is the **evaluation** problem in HMMs
- ► What portion of the sequence was generated with the fair die, and what portion with the loaded die?
  - ► This is the **decoding** question in HMMs
- ► How biased is the loaded die? How fair is the fair die? How often does the casino player change from fair to loaded and back?
  - This is the learning question in HMMs

# HMM Example

• Observed sequence:  $\{O_t\}_{t=1}^T$ 

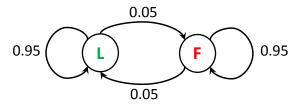

• Hidden sequence  $\{S_t\}_{t=1}^T$  or segmentation):

# State Space Representation

Switch between **F** and **L** once every 20 turns (1/20 = 0.05)

#### **HMM Parameters**

Initial probs
Transition probs

**Emission probabilities** 

$$\begin{split} P(S_1 = L) &= 0.5 = P(S_1 = F) \\ P(S_t = L/F | S_{t-1} = L/F) &= 0.95 \\ P(S_t = F/L | S_{t-1} = L/F) &= 0.05 \\ P(O_t = y | S_t = F) &= 1/6 \qquad y = 1,2,3,4,5,6 \\ P(O_t = y | S_t = L) &= 1/10 \qquad y = 1,2,3,4,5 \\ &= 1/2 \qquad y = 6 \end{split}$$

# Three main problems in HMMs

- ▶ Evaluation: Given HMM parameters & observation seqn  $\{O_t\}_{t=1}^T$ 
  - find the probability of observed sequence
- ▶ **Decoding**: Given HMM parameters & observation seqn  $\{O_t\}_{t=1}^T$ 
  - ▶ find most probable sequence of hidden states
- ▶ **Learning**: Given HMM with unknown parameters and  $\{O_t\}_{t=1}^T$  observation sequence
  - find parameters that maximize likelihood of observed data

# **HMM Algorithms**

- Evaluation
  - What is the probability of the observed sequence? Forward Algorithm
- Decoding
  - What is the probability that the third roll was loaded given the observed sequence? Forward-Backward Algorithm
  - What is the most likely die sequence given the observed sequence? Viterbi Algorithm
- Learning
  - Under what parameterization is the observed sequence most probable? Baum-Welch Algorithm (EM)

#### Evaluation Problem

Given HMM parameters  $p(S_1), p(S_t \mid S_{t-1}), p(O_t \mid S_t)$  & observation sequence  $\{O_t\}_{t=1}^T$ 

find probability of observed sequence 
$$p(\{O_t\}_{t=1}^T) \ = \ \sum_{S_1,...,S_T} p(\{O_t\}_{t=1}^T, \{S_t\}_{t=1}^T) \qquad \begin{matrix} S_1 & S_2 & S_{T-1} & S_T \\ O_1 & O_2 & O_{T-1} & O_T \end{matrix}$$
 
$$= \ \sum_{S_1,...,S_T} p(S_1) \prod_{t=2}^T p(S_t|S_{t-1}) \prod_{t=1}^T p(O_t|S_t)$$

requires summing over all possible hidden state values at all times – K<sup>T</sup> exponential # terms!

Instead: 
$$p(\{O_t\}_{t=1}^T) = \sum_k p(\{O_t\}_{t=1}^T, S_T = k)$$
 
$$\alpha_{\mathsf{T}}^{\mathsf{k}} \quad \textit{Compute recursively}$$

# Forward Probability

$$p(\{O_t\}_{t=1}^T) = \sum_k p(\{O_t\}_{t=1}^T, S_T = k) = \sum_k \alpha_T^k$$

## Compute forward probability $\alpha_t^k$ recursively over t

$$\alpha_t^k := p(O_1, \dots, O_t, S_t = k)$$

Introduce S<sub>t-1</sub>

. Chain rule

Markov assumption

$$= p(O_t|S_t = k) \sum_{i} \alpha_{t-1}^i p(S_t = k|S_{t-1} = i)$$

# Forward Algorithm

Can compute  $\alpha_t^k$  for all k, t using dynamic programming:

- Initialize:  $\alpha_1^k = p(O_1 \mid S_1 = k)p(S_1 = k) \ \forall k$
- lterate: for  $t = 2, \dots, T$

$$\alpha_t^k = p(O_t \mid S_t = k) \sum_i \alpha_{t-1}^i p(S_t = k \mid S_{t-1} = i) \ \forall k$$

► Termination:

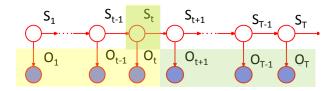

$$p\left(\left\{O_t\right\}_{t=1}^T\right) = \sum_k \alpha_T^k$$

# Decoding Problem 1

Given HMM parameters  $p(S_1), p(S_t|S_{t-1}), p(O_t|S_t)$  & observation sequence  $\{O_t\}_{t=1}^T$ 

find probability that hidden state at time t was k  $p(S_t = k | \{O_t\}_{t=1}^T)$ 

$$\begin{array}{lll} p(S_t=k,\{O_t\}_{t=1}^T) & = & p(O_1,\ldots,O_t,S_t=k,O_{t+1},\ldots,O_T) \\ & = & p(O_1,\ldots,O_t,S_t=k)p(O_{t+1},\ldots,O_T|S_t=k) \\ \\ \text{Compute recursively} & & \alpha_t^{\mathsf{k}} & \beta_t^{\mathsf{k}} \end{array}$$

# **Backward Probability**

$$p(S_t = k, \{O_t\}_{t=1}^T) = p(O_1, \dots, O_t, S_t = k)p(O_{t+1}, \dots, O_T | S_t = k) = \alpha_t^k \beta_t^k$$

#### Compute forward probability $\beta_t^k$ recursively over t

$$\beta_t^k := p(O_{t+1}, \dots, O_T | S_t = k)$$
 
$$\text{Introduce } S_{t+1}$$
 
$$\vdots$$
 
$$\text{Chain rule}$$

Markov assumption

$$= \sum_{i} p(S_{t+1} = i|S_t = k)p(O_{t+1}|S_{t+1} = i)\beta_{t+1}^{i}$$

# Backward Algorithm

Can compute  $\beta_t^k \ \forall k, t$  using dynamic programming:

- ▶ Initialize:  $\beta_T^k = 1 \ \forall k$
- ▶ Iterate: for t = T-1, ..., 1

$$\beta_t^k = \sum_i p(S_{t+1} = i \mid S_t = k) p(O_{t+1} \mid S_{t+1} = i) \beta_{t+1}^i \ \forall k$$

► Termination:  $p(S_t = k, \{O_t\}_{t=1}^T) = \alpha_t^k \beta_t^k$ 

$$p(S_t = k \mid \{O_t\}_{t=1}^T) = \frac{p(S_t = k, \{O_t\}_{t=1}^T)}{p(\{O_t\}_{t=1}^T)} = \frac{\alpha_t^k \beta_t^k}{\sum_i \alpha_t^i \beta_t^i}$$

# Most likely state vs. Most likely sequence

Most likely state assignment at time t

$$\arg\max_{k} p(S_t = k \mid \{O_t\}_{t=1}^T) = \arg\max_{k} \alpha_t^k \beta_t^k$$

- ► E.g. Which die was most likely used by the casino in the third roll given the observed sequence?
- Most likely assignment of state sequence

$$\arg\max_{\{S_t\}_{t=1}^T} p(\{S_t\}_{t=1}^T \mid \{O_t\}_{t=1}^T)$$

► E.g. What was the most likely sequence of die rolls used by the casino given the observed sequence?

#### Not the same!

# Decoding Problem 2

Given HMM parameters  $p(S_1), p(S_t|S_{t-1}), p(O_t|S_t)$  & observation sequence  $\{O_t\}_{t=1}^T$ 

find most likely assignment of state sequence

$$\arg\max_{\{S_t\}_{t=1}^T} p(\{S_t\}_{t=1}^T | \{O_t\}_{t=1}^T) = \arg\max_{\{S_t\}_{t=1}^T} p(\{S_t\}_{t=1}^T, \{O_t\}_{t=1}^T)$$

$$= \arg\max_{k} \max_{\{S_t\}_{t=1}^{T-1}} p(S_T = k, \{S_t\}_{t=1}^{T-1}, \{O_t\}_{t=1}^T)$$

$$\bigvee_{\mathsf{T}}^{\mathsf{K}}$$

Compute recursively

 $V_T^k$  - probability of most likely sequence of states ending at state  $S_T = k$ 

# Viterbi Decoding

$$\max_{\{S_t\}_{t=1}^T} p(\{S_t\}_{t=1}^T, \{O_t\}_{t=1}^T) = \max_k V_T^k$$

#### Compute probability V<sup>k</sup> recursively over t

$$V_t^k := \max_{S_1, \dots, S_{t-1}} p(S_t = k, S_1, \dots, S_{t-1}, O_1, \dots, O_t)$$

$$= p(O_t|S_t = k) \max_{i} p(S_t = k|S_{t-1} = i)V_{t-1}^i$$

# Viterbi Algorithm

Can compute  $V_t^k \ \forall k, t$  using dynamic programming:

- Initialize:  $V_1^k = p(O_1|S_1=k)p(S_1=k)$  for all k
- Iterate: for t = 2, ..., T

$$V_t^k = p(O_t|S_t = k) \max_i p(S_t = k|S_{t-1} = i)V_{t-1}^i$$
 for all k

• Termination: 
$$\max_{\{S_t\}_{t=1}^T} p(\{S_t\}_{t=1}^T, \{O_t\}_{t=1}^T) = \max_k V_T^k$$

Traceback: 
$$S_T^* = \arg\max_k V_T^k$$
 
$$S_{t-1}^* = \arg\max_i p(S_t^*|S_{t-1}=i)V_{t-1}^i$$

# Computational complexity

What is the running time for Forward, Forward-Backward, Viterbi?

$$\alpha_t^k = q_k^{O_t} \sum_i \alpha_{t-1}^i p_{i,k}$$

$$\beta_t^k = \sum_{i} p_{k,i} q_i^{O_{t+1}} \beta_{t+1}^i$$

$$V_t^k = q_k^{O_t} \max_{i} p_{i,k} V_{t-1}^i$$

 $O(K^2T)$  linear in T instead of  $O(K^T)$  exponential in T!

# Learning Problem

- Given HMM with:
  - unknown parameters  $\theta = \{\{\pi_i\}, \{p_{ij}\}, \{q_i^k\}\}$
  - observation sequence  $O = \{O_t\}_{t=1}^T$
- Find parameters that maximize likelihood of observed data

  - ▶ But likelihood doesn't factorize since observations not i.i.d.
  - hidden variables: state sequence
- ► EM (Baum-Welch) Algorithm:
  - ► E-step: Fix parameters, find expected state assignments
  - ► M-step: Fix expected state assignments, update parameters

# Baum-Welch (EM) Algorithm

E-step – Fix parameters, find expected state assignments

$$\gamma_i(t) = p(S_t = i | O, heta) = rac{lpha_t^i eta_t^i}{\sum_j lpha_t^j eta_t^j}$$

Forward-Backward algorithm

$$\begin{aligned} \xi_{ij}(t) &= p(S_{t-1} = i, S_t = j | O, \theta) \\ &= \frac{p(S_{t-1} = i | O, \theta) p(S_t = j, O_t, \dots, O_T | S_{t-1} = i, \theta)}{p(O_t, \dots, O_T | S_{t-1} = i, \theta)} \\ &= \frac{\gamma_i(t-1) \ p_{ij} \ q_j^{O_t} \ \beta_t^j}{\beta_{t-1}^i} \end{aligned}$$

# Baum-Welch (EM) Algorithm

▶ Start with random initialization of parameters

#### E-step

$$\gamma_i(t) = p(S_t = i | O, heta)$$
  $\xi_{ij}(t) = p(S_{t-1} = i, S_t = j | O, heta)$ 

 $\sum_{t=1}^{T} \gamma_i(t) = \text{expected \# times}$  in state i  $\sum_{t=1}^{T-1} \gamma_i(t) = \text{expected \# transitions}$  from state i  $\sum_{t=1}^{T-1} \xi_{ij}(t) = \text{expected \# transitions}$ 

from state i to j

M-step

$$\pi_i = \gamma_i(1)$$

$$p_{ij} = \frac{\sum_{t=1}^{T-1} \xi_{ij}(t)}{\sum_{t=1}^{T-1} \gamma_i(t)}$$

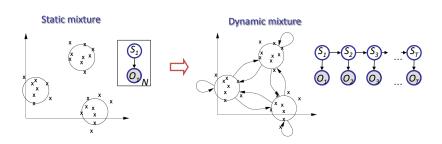

$$q_i^k = \frac{\sum_{t=1}^T \delta_{O_t = k} \gamma_i(t)}{\sum_{t=1}^T \gamma_i(t)}$$

#### Some connections

► HMM & Dynamic Mixture Models

$$p(O_t) = \sum_{S_t} p(O_t \mid S_t) p(S_t)$$

 Choice of mixture component depends on choice of components for previous observations

#### Connections to Other Models

#### **ODEs**

- ▶ If we average over many individuals following a Markov process, we get a system of ODEs
- Multiple Markov models can give rise to the same ODEs due to transition probabilities

#### Latent variable models

Many techniques we've talked about separate the data from the process generating it

#### HMMs: What You Should Know

- Useful for modeling sequential data with few parameters using discrete hidden states that satisfy Markov assumption
- Representation
  - Initial probability
  - Transition probabilities
  - Emission probabilities
- Algorithms for inference and learning in HMMs
  - Computing marginal likelihood of the observed sequence: forward algorithm
  - Predicting a single hidden state: forward-backward
  - Predicting an entire sequence of hidden states: Viterbi
  - Learning HMM parameters: an EM algorithm known as Baum-Welch

# Stochastic State Transitions Give Rise to Phenotypic Equilibrium in Populations of Cancer Cells

Piyush B. Gupta, <sup>1,6,\*</sup> Christine M. Fillmore, <sup>2</sup> Guozhi Jiang, <sup>1</sup> Sagi D. Shapira, <sup>1</sup> Kai Tao, <sup>3</sup> Charlotte Kuperwasser, <sup>2,3</sup> and Eric S. Lander<sup>1,4,5,\*</sup>

#### SUMMARY

Cancer cells within individual tumors often exist in distinct phenotypic states that differ in functional attributes. While cancer cell populations typically display distinctive equilibria in the proportion of cells in various states, the mechanisms by which this occurs are poorly understood. Here, we study the

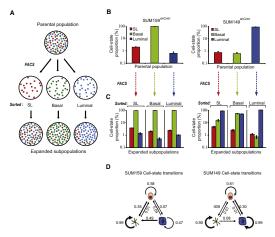

Figure 2. Determination of Breast Cancer Cell-State Transition Probabilities from Population Cell-State Proportions

- (A) Schematic of experimental procedure used to determine cell-state transition dynamics.
   (B) Proportions of cell-states in parental SUM159<sup>shCntrl</sup> and SUM149<sup>shCntrl</sup> breast cancer lines.
- (C) Cellular subpopulations in stem-like (SL), basal, or luminal states were isolated by FACS with antibodies directed against the CD44, CD24, and EpCAM cell-surface antigens. Bar charts show the proportion of cells in each cell-differentiation state as assessed by FACS after in vitro culture for 6 days.
- (D) Lineage hierarchies for the SUM159<sup>arCost</sup> and SUM149<sup>arCost</sup> lines were calculated from the data in (O). The corresponding cell-state transition probabilities for each cell line are shown. Solid arrows denote transition probabilities greater than 0.1. Dashed arrows denote transition probabilities between 0.01 and 0.1. See also Figure S1.

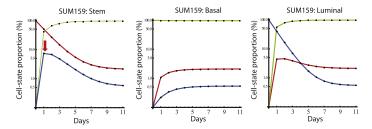

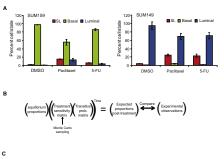

Figure 3. Prediction of Cell-State Dynamics with the Stochastic Cell-State Transition Model

The transition probabilities determined for the SUM159 line were used to compute the expected cell-state proportions over time for isolated subpopulations of stem-like, basal, or luminal cells. For all three isolated subpopulations, an eventual return to equilibrium cell-state proportions is predicted. The model predicts a transient increase in the proportion of SUM159 luminal cells one day after isolation of a stem-like subpopulation (red arrow).

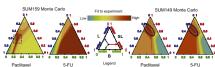

Figure 4. Analysis of Chemical Treatment Sensitivities by Monte Carlo Simulation with the Stochastic Cell-State Transition Model
(A) Cell-state proportions after a 6 day treatment with either pacificated or 5-FU are shown for SUM159 and SUM149 populations.

(B) A schematic showing low differential chemical treatment sensibilities can be incoporated into the Markov stochastic model. The material probabilities of premating the probabilities of premating the probabilities of premating value (and probabilities of premating value) and probabilities of premating value (and probabilities of premating value) and probabilities of premating value (and probabilities of premating value) and probabilities of premating value (and probabilities of premating value) and probabilities of premating value (and probabilities) and value (and probabilities) and value).

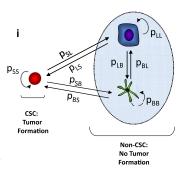

(C) The results of Monte Carlo simulation, above as terrary density contour plots in which coloration represents the normalized difference (see the three perfectives for the metric used) between experimentally observed and predicted cell scale proportions (solving chemical treatment. The thickard monitor is within the triangle simples were sampled, each representing a distinct choice of differential viability vector, (v<sub>w</sub>, v<sub>w</sub>, v<sub>h</sub>), with entries ranging from zero (sensitive) to one effective for the contraction of th

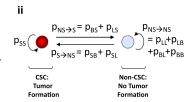

# CSC model I CSC: Tumor Formation Formation

#### Figure 5. Two Distinct Models of Cancer Cell Populations

In the existing paradigm (model I), CSCs give rise to non-CSCs but not vice versa, resulting in a hierarchical cell-lineage structure reflective of normal tissue biology. We propose an alternative scenario (model II) in which there is bidirectional interconversion between CSC and non-CSC states. The rates of transition between cell states, which vary across distinct cancer cell populations, can be computed with the Markov modeling approach described in the main text and Experimental Procedures.

#### CSC model II

# Example 2: Sequence Prediction

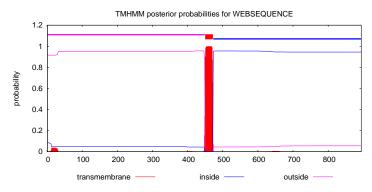

Figure: AXL prediction

#### **Implementation**

```
from hmmlearn.hmm import GaussianHMM
# Make an HMM instance and execute fit
model = GaussianHMM(n_components=4,
                    covariance_type="diag",
                    n iter=1000).fit(X)
# Predict the optimal sequence of internal hidden state
hidden_states = model.predict(X)
print("Transition matrix")
print(model.transmat )
print("Means and vars of each hidden state")
for i in range(model.n components):
    print("{0}th hidden state".format(i))
    print("mean = ", model.means_[i])
    print("var = ", np.diag(model.covars [i]))
```

#### **Implementation**

Find most likely state sequence corresponding to X.

model.decode(X, algorithm=None)

algorithm: Decoder algorithm. Must be one of "viterbi" or "map". "viterbi" default.

Provides logprob and state\_sequence.
